## 1 Ad Hoc Overloading

```
theory Adhoc_Overloading_Examples
imports
  Main
  HOL-Library.Infinite_Set
  HOL-Library.Adhoc_Overloading
begin
```

Adhoc overloading allows to overload a constant depending on its type. Typically this involves to introduce an uninterpreted constant (used for input and output) and then add some variants (used internally).

## 1.1 Plain Ad Hoc Overloading

Consider the type of first-order terms.

```
datatype ('a, 'b) term =
  Var 'b |
  Fun 'a ('a, 'b) term list
```

The set of variables of a term might be computed as follows.

```
fun term_vars :: ('a, 'b) term  $\Rightarrow$  'b set where
  term_vars (Var x) = {x} |
  term_vars (Fun f ts) =  $\bigcup$ (set (map term_vars ts))
```

However, also for *rules* (i.e., pairs of terms) and term rewrite systems (i.e., sets of rules), the set of variables makes sense. Thus we introduce an unspecified constant *vars*.

```
consts vars :: 'a  $\Rightarrow$  'b set
```

Which is then overloaded with variants for terms, rules, and TRSs.

```
adhoc_overloading
  vars term_vars
```

```
value [nbe] vars (Fun "f" [Var 0, Var 1])
```

```
fun rule_vars :: ('a, 'b) term  $\times$  ('a, 'b) term  $\Rightarrow$  'b set where
  rule_vars (l, r) = vars l  $\cup$  vars r
```

```
adhoc_overloading
  vars rule_vars
```

```
value [nbe] vars (Var 1, Var 0)
```

```
definition trs_vars :: (('a, 'b) term  $\times$  ('a, 'b) term) set  $\Rightarrow$  'b set where
  trs_vars R =  $\bigcup$ (rule_vars ` R)
```

```
adhoc_overloading
  vars trs_vars
```

```
value [nbe] vars {(Var 1, Var 0)}
```

Sometimes it is necessary to add explicit type constraints before a variant can be determined.

```
value vars (R :: (('a, 'b) term  $\times$  ('a, 'b) term) set)
```

It is also possible to remove variants.

```
no_adhoc_overloading
  vars term_vars rule_vars
```

As stated earlier, the overloaded constant is only used for input and output. Internally, always a variant is used, as can be observed by the configuration option `show_variants`.

```
adhoc_overloading
  vars term_vars
```

```
declare [[show_variants]]
```

```
term vars (Var 1)
```

## 1.2 Adhoc Overloading inside Locales

As example we use permutations that are parametrized over an atom type `'a`.

```
definition perms :: ('a ⇒ 'a) set where
  perms = {f. bij f ∧ finite {x. f x ≠ x}}
```

```
typedef 'a perm = perms :: ('a ⇒ 'a) set
  ⟨proof⟩
```

First we need some auxiliary lemmas.

```
lemma permsI [Pure.intro]:
  assumes bij f and MOST x. f x = x
  shows f ∈ perms
  ⟨proof⟩
```

```
lemma perms_imp_bij:
  f ∈ perms ⇒ bij f
  ⟨proof⟩
```

```
lemma perms_imp_MOST_eq:
  f ∈ perms ⇒ MOST x. f x = x
  ⟨proof⟩
```

```
lemma id_perms [simp]:
  id ∈ perms
  (λx. x) ∈ perms
  ⟨proof⟩
```

```
lemma perms_comp [simp]:
  assumes f: f ∈ perms and g: g ∈ perms
  shows (f ∘ g) ∈ perms
  ⟨proof⟩
```

```
lemma perms_inv:
  assumes f: f ∈ perms
  shows inv f ∈ perms
  ⟨proof⟩
```

```

lemma bij_Rep_perm: bij (Rep_perm p)
  <proof>

instantiation perm :: (type) group_add
begin

  definition 0 = Abs_perm id
  definition - p = Abs_perm (inv (Rep_perm p))
  definition p + q = Abs_perm (Rep_perm p ∘ Rep_perm q)
  definition (p1:'a perm) - p2 = p1 + - p2

  lemma Rep_perm_0: Rep_perm 0 = id
    <proof>

  lemma Rep_perm_add:
    Rep_perm (p1 + p2) = Rep_perm p1 ∘ Rep_perm p2
    <proof>

  lemma Rep_perm_uminus:
    Rep_perm (- p) = inv (Rep_perm p)
    <proof>

  instance
    <proof>

end

lemmas Rep_perm_simps =
  Rep_perm_0
  Rep_perm_add
  Rep_perm_uminus

```

## 2 Permutation Types

We want to be able to apply permutations to arbitrary types. To this end we introduce a constant *PERMUTE* together with convenient infix syntax.

```
consts PERMUTE :: 'a perm ⇒ 'b ⇒ 'b (infixr · 75)
```

Then we add a locale for types '*b*' that support application of permutations.

```

locale permute =
  fixes permute :: 'a perm ⇒ 'b ⇒ 'b
  assumes permute_zero [simp]: permute 0 x = x
  and permute_plus [simp]: permute (p + q) x = permute p (permute q x)
begin

adhoc_overloading
  PERMUTE permute

```

```
end
```

Permuting atoms.

```
definition permute_atom :: 'a perm ⇒ 'a ⇒ 'a where
  permute_atom p a = (Rep_perm p) a
```

```
adhoc_overloading
```

*PERMUTE permute\_atom*

```
interpretation atom_permute: permute permute_atom
  ⟨proof⟩
```

Permuting permutations.

```
definition permute_perm :: 'a perm ⇒ 'a perm ⇒ 'a perm where
  permute_perm p q = p + q - p
```

```
adhoc_overloading
```

*PERMUTE permute\_perm*

```
interpretation perm_permute: permute permute_perm
  ⟨proof⟩
```

Permuting functions.

```
locale fun_permute =
  dom: permute perm1 + ran: permute perm2
  for perm1 :: 'a perm ⇒ 'b ⇒ 'b
  and perm2 :: 'a perm ⇒ 'c ⇒ 'c
begin
```

```
adhoc_overloading
```

*PERMUTE perm1 perm2*

```
definition permute_fun :: 'a perm ⇒ ('b ⇒ 'c) ⇒ ('b ⇒ 'c) where
  permute_fun p f = (λx. p ∘ (f (−p ∘ x)))
```

```
adhoc_overloading
```

*PERMUTE permute\_fun*

```
end
```

```
sublocale fun_permute ⊆ permute permute_fun
  ⟨proof⟩
```

```
lemma (Abs_perm id :: nat perm) ∙ Suc 0 = Suc 0
  ⟨proof⟩
```

```
interpretation atom_fun_permute: fun_permute permute_atom permute_atom
  ⟨proof⟩
```

```

adhoc_overloading
PERMUTE atom_fun_permute.permute_fun

lemma (Abs_perm id :: 'a perm) · id = id
  ⟨proof⟩

end

```

### 3 A Tail-Recursive, Stack-Based Ackermann's Function

**theory** Ackermann imports HOL-Library.Multiset\_Order HOL-Library.Product\_Lexorder

**begin**

This theory investigates a stack-based implementation of Ackermann's function. Let's recall the traditional definition, as modified by Rózsa Péter and Raphael Robinson.

```

fun ack :: [nat,nat] ⇒ nat where
  ack 0 n          = Suc n
  | ack (Suc m) 0   = ack m 1
  | ack (Suc m) (Suc n) = ack m (ack (Suc m) n)

```

#### 3.1 Example of proving termination by reasoning about the domain

The stack-based version uses lists.

```

function (domintros) ackloop :: nat list ⇒ nat where
  ackloop (n # 0 # l)      = ackloop (Suc n # l)
  | ackloop (0 # Suc m # l) = ackloop (1 # m # l)
  | ackloop (Suc n # Suc m # l) = ackloop (n # Suc m # m # l)
  | ackloop [m] = m
  | ackloop [] = 0
  ⟨proof⟩

```

The key task is to prove termination. In the first recursive call, the head of the list gets bigger while the list gets shorter, suggesting that the length of the list should be the primary termination criterion. But in the third recursive call, the list gets longer. The idea of trying a multiset-based termination argument is frustrated by the second recursive call when  $m = 0$ : the list elements are simply permuted.

Fortunately, the function definition package allows us to define a function and only later identify its domain of termination. Instead, it makes all the

recursion equations conditional on satisfying the function's domain predicate. Here we shall eventually be able to show that the predicate is always satisfied.

```
ackloop_dom (Suc n # l) ==> ackloop_dom (n # 0 # l)
ackloop_dom (Suc 0 # m # l) ==> ackloop_dom (0 # Suc m # l)
ackloop_dom (n # Suc m # m # l) ==> ackloop_dom (Suc n # Suc m # l)
ackloop_dom [m]
ackloop_dom []
```

```
declare ackloop.domintros [simp]
```

Termination is trivial if the length of the list is less then two. The following lemma is the key to proving termination for longer lists.

```
lemma ackloop_dom (ack m n # l) ==> ackloop_dom (n # m # l)
⟨proof⟩
```

The proof above (which actually is unused) can be expressed concisely as follows.

```
lemma ackloop_dom_longer:
  ackloop_dom (ack m n # l) ==> ackloop_dom (n # m # l)
⟨proof⟩
```

This function codifies what *ackloop* is designed to do. Proving the two functions equivalent also shows that *ackloop* can be used to compute Ackermann's function.

```
fun acklist :: nat list => nat where
  acklist (n#m#l) = acklist (ack m n # l)
| acklist [m] = m
| acklist [] = 0
```

The induction rule for *acklist* is

```
[[A n m l. P (ack m n # l) ==> P (n # m # l); A m. P [m]; P []]] ==> P a0
```

```
.
```

```
lemma ackloop_dom: ackloop_dom l
⟨proof⟩
```

```
termination ackloop
⟨proof⟩
```

This result is trivial even by inspection of the function definitions (which faithfully follow the definition of Ackermann's function). All that we needed was termination.

```
lemma ackloop_acklist: ackloop l = acklist l
```

$\langle proof \rangle$

**theorem**  $ack: ack\ m\ n = ackloop\ [n,m]$   
 $\langle proof \rangle$

### 3.2 Example of proving termination using a multiset ordering

This termination proof uses the argument from Nachum Dershowitz and Zohar Manna. Proving termination with multiset orderings. Communications of the ACM 22 (8) 1979, 465–476.

Setting up the termination proof. Note that Dershowitz had  $z$  as a global variable. The top two stack elements are treated differently from the rest.

```
fun ack_mset :: nat list => (nat×nat) multiset where
  ack_mset [] = {#}
  | ack_mset [x] = {#}
  | ack_mset (z#y#l) = mset ((y,z) # map (λx. (Suc x, 0)) l)

lemma case1: ack_mset (Suc n # l) < add_mset (0,n) {# (Suc x, 0)}. x ∈# mset l #
  ⟨proof⟩
```

The stack-based version again. We need a fresh copy because we've already proved the termination of  $ackloop$ .

```
function Ackloop :: nat list => nat where
  Ackloop (n # 0 # l)      = Ackloop (Suc n # l)
  | Ackloop (0 # Suc m # l) = Ackloop (1 # m # l)
  | Ackloop (Suc n # Suc m # l) = Ackloop (n # Suc m # m # l)
  | Ackloop [m] = m
  | Ackloop [] = 0
  ⟨proof⟩
```

In each recursive call, the function  $ack\_mset$  decreases according to the multiset ordering.

**termination**  
 $\langle proof \rangle$

Another shortcut compared with before: equivalence follows directly from this lemma.

**lemma**  $Ackloop\_ack: Ackloop (n # m # l) = Ackloop (ack\ m\ n # l)$   
 $\langle proof \rangle$

**theorem**  $ack\ m\ n = Ackloop\ [n,m]$   
 $\langle proof \rangle$

**end**

## 4 Cantor's Theorem

```
theory Cantor
  imports Main
begin
```

### 4.1 Mathematical statement and proof

Cantor's Theorem states that there is no surjection from a set to its powerset. The proof works by diagonalization. E.g. see

- <http://mathworld.wolfram.com/CantorDiagonalMethod.html>
- [https://en.wikipedia.org/wiki/Cantor%27s\\_diagonal\\_argument](https://en.wikipedia.org/wiki/Cantor%27s_diagonal_argument)

```
theorem Cantor: ∉ f :: 'a ⇒ 'a set. ∀ A. ∃ x. A = f x
⟨proof⟩
```

### 4.2 Automated proofs

These automated proofs are much shorter, but lack information why and how it works.

```
theorem ∉ f :: 'a ⇒ 'a set. ∀ A. ∃ x. f x = A
⟨proof⟩
```

```
theorem ∉ f :: 'a ⇒ 'a set. ∀ A. ∃ x. f x = A
⟨proof⟩
```

### 4.3 Elementary version in higher-order predicate logic

The subsequent formulation bypasses set notation of HOL; it uses elementary  $\lambda$ -calculus and predicate logic, with standard introduction and elimination rules. This also shows that the proof does not require classical reasoning.

```
lemma iff_contradiction:
  assumes *: ¬ A ↔ A
  shows False
⟨proof⟩
```

```
theorem Cantor': ∉ f :: 'a ⇒ 'a ⇒ bool. ∀ A. ∃ x. A = f x
⟨proof⟩
```

### 4.4 Classic Isabelle/HOL example

The following treatment of Cantor's Theorem follows the classic example from the early 1990s, e.g. see the file 92/HOL/ex/set.ML in Isabelle92 or

[2, §18.7]. The old tactic scripts synthesize key information of the proof by refinement of schematic goal states. In contrast, the Isar proof needs to say explicitly what is proven.

Cantor's Theorem states that every set has more subsets than it has elements. It has become a favourite basic example in pure higher-order logic since it is so easily expressed:

$$\forall f::\alpha \Rightarrow \alpha \Rightarrow \text{bool}. \exists S::\alpha \Rightarrow \text{bool}. \forall x::\alpha. f x \neq S$$

Viewing types as sets,  $\alpha \Rightarrow \text{bool}$  represents the powerset of  $\alpha$ . This version of the theorem states that for every function from  $\alpha$  to its powerset, some subset is outside its range. The Isabelle/Isar proofs below uses HOL's set theory, with the type  $\alpha \text{ set}$  and the operator  $\text{range} :: (\alpha \Rightarrow \beta) \Rightarrow \beta \text{ set}$ .

```
theorem  $\exists S. S \notin \text{range}(f :: 'a \Rightarrow 'a \text{ set})$ 
   $\langle \text{proof} \rangle$ 
```

How much creativity is required? As it happens, Isabelle can prove this theorem automatically using best-first search. Depth-first search would diverge, but best-first search successfully navigates through the large search space. The context of Isabelle's classical prover contains rules for the relevant constructs of HOL's set theory.

```
theorem  $\exists S. S \notin \text{range}(f :: 'a \Rightarrow 'a \text{ set})$ 
   $\langle \text{proof} \rangle$ 
```

end

## 5 Coherent Logic Problems

```
theory Coherent
imports Main
begin
```

### 5.1 Equivalence of two versions of Pappus' Axiom

```
no_notation
  comp (infixl o 55) and
  relcomp (infixr O 75)

lemma p1p2:
  assumes col a b c l  $\wedge$  col d e f m
  and col b f g n  $\wedge$  col c e g o
  and col b d h p  $\wedge$  col a e h q
  and col c d i r  $\wedge$  col a f i s
  and el n o  $\Longrightarrow$  goal
  and el p q  $\Longrightarrow$  goal
```

and  $\text{el } s \ r \implies \text{goal}$   
 and  $\bigwedge A. \text{el } A \ A \implies \text{pl } g \ A \implies \text{pl } h \ A \implies \text{pl } i \ A \implies \text{goal}$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } A \ D$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } B \ D$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } C \ D$   
 and  $\bigwedge A \ B. \text{pl } A \ B \implies \text{ep } A \ A$   
 and  $\bigwedge A \ B. \text{ep } A \ B \implies \text{ep } B \ A$   
 and  $\bigwedge A \ B \ C. \text{ep } A \ B \implies \text{ep } B \ C \implies \text{ep } A \ C$   
 and  $\bigwedge A \ B. \text{pl } A \ B \implies \text{el } B \ B$   
 and  $\bigwedge A \ B. \text{el } A \ B \implies \text{el } B \ A$   
 and  $\bigwedge A \ B \ C. \text{el } A \ B \implies \text{el } B \ C \implies \text{el } A \ C$   
 and  $\bigwedge A \ B \ C. \text{ep } A \ B \implies \text{pl } B \ C \implies \text{pl } A \ C$   
 and  $\bigwedge A \ B \ C. \text{pl } A \ B \implies \text{el } B \ C \implies \text{pl } A \ C$   
 and  $\bigwedge A \ B \ C \ D \ E \ F \ G \ H \ I \ J \ K \ L \ M \ N \ O \ P \ Q.$   
 $\quad \text{col } A \ B \ C \ D \implies \text{col } E \ F \ G \ H \implies \text{col } B \ G \ I \ J \implies \text{col } C \ F \ I \ K \implies$   
 $\quad \text{col } B \ E \ L \ M \implies \text{col } A \ F \ L \ N \implies \text{col } C \ E \ O \ P \implies \text{col } A \ G \ O \ Q \implies$   
 $\quad (\exists R. \text{col } I \ L \ O \ R) \vee \text{pl } A \ H \vee \text{pl } B \ H \vee \text{pl } C \ H \vee \text{pl } E \ D \vee \text{pl } F \ D \vee \text{pl}$   
 $G \ D$   
 and  $\bigwedge A \ B \ C \ D. \text{pl } A \ B \implies \text{pl } A \ C \implies \text{pl } D \ B \implies \text{pl } D \ C \implies \text{ep } A \ D \vee \text{el}$   
 $B \ C$   
 and  $\bigwedge A \ B. \text{ep } A \ A \implies \text{ep } B \ B \implies \exists C. \text{pl } A \ C \wedge \text{pl } B \ C$   
**shows goal** ⟨proof⟩

**lemma**  $p2p1$ :  
**assumes**  $\text{col } a \ b \ c \ l \wedge \text{col } d \ e \ f \ m$   
 and  $\text{col } b \ f \ g \ n \wedge \text{col } c \ e \ g \ o$   
 and  $\text{col } b \ d \ h \ p \wedge \text{col } a \ e \ h \ q$   
 and  $\text{col } c \ d \ i \ r \wedge \text{col } a \ f \ i \ s$   
 and  $\text{pl } a \ m \implies \text{goal}$   
 and  $\text{pl } b \ m \implies \text{goal}$   
 and  $\text{pl } c \ m \implies \text{goal}$   
 and  $\text{pl } d \ l \implies \text{goal}$   
 and  $\text{pl } e \ l \implies \text{goal}$   
 and  $\text{pl } f \ l \implies \text{goal}$   
 and  $\bigwedge A. \text{pl } g \ A \implies \text{pl } h \ A \implies \text{pl } i \ A \implies \text{goal}$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } A \ D$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } B \ D$   
 and  $\bigwedge A \ B \ C \ D. \text{col } A \ B \ C \ D \implies \text{pl } C \ D$   
 and  $\bigwedge A \ B. \text{pl } A \ B \implies \text{ep } A \ A$   
 and  $\bigwedge A \ B. \text{ep } A \ B \implies \text{ep } B \ A$   
 and  $\bigwedge A \ B \ C. \text{ep } A \ B \implies \text{ep } B \ C \implies \text{ep } A \ C$   
 and  $\bigwedge A \ B. \text{pl } A \ B \implies \text{el } B \ B$   
 and  $\bigwedge A \ B. \text{el } A \ B \implies \text{el } B \ A$   
 and  $\bigwedge A \ B \ C. \text{el } A \ B \implies \text{el } B \ C \implies \text{el } A \ C$   
 and  $\bigwedge A \ B \ C. \text{ep } A \ B \implies \text{pl } B \ C \implies \text{pl } A \ C$

 and  $\bigwedge A \ B \ C \ D \ E \ F \ G \ H \ I \ J \ K \ L \ M \ N \ O \ P \ Q.$   
 $\quad \text{col } A \ B \ C \ J \implies \text{col } D \ E \ F \ K \implies \text{col } B \ F \ G \ L \implies \text{col } C \ E \ G \ M \implies$   
 $\quad \text{col } B \ D \ H \ N \implies \text{col } A \ E \ H \ O \implies \text{col } C \ D \ I \ P \implies \text{col } A \ F \ I \ Q \implies$

```

 $(\exists R. \text{col } G H I R) \vee \text{el } L M \vee \text{el } N O \vee \text{el } P Q$ 
and  $\bigwedge A B C D. \text{pl } C A \implies \text{pl } C B \implies \text{pl } D A \implies \text{pl } D B \implies \text{ep } C D \vee \text{el}$ 
 $A B$ 
and  $\bigwedge A B C. \text{ep } A A \implies \text{ep } B B \implies \exists C. \text{pl } A C \wedge \text{pl } B C$ 
shows goal ⟨proof⟩

```

## 5.2 Preservation of the Diamond Property under reflexive closure

```

lemma diamond:
  assumes reflexive_rewrite a b reflexive_rewrite a c
  and  $\bigwedge A. \text{reflexive\_rewrite } b A \implies \text{reflexive\_rewrite } c A \implies \text{goal}$ 
  and  $\bigwedge A. \text{equalish } A A$ 
  and  $\bigwedge A B. \text{equalish } A B \implies \text{equalish } B A$ 
  and  $\bigwedge A B C. \text{equalish } A B \implies \text{reflexive\_rewrite } B C \implies \text{reflexive\_rewrite } A$ 
   $C$ 
  and  $\bigwedge A B. \text{equalish } A B \implies \text{reflexive\_rewrite } A B$ 
  and  $\bigwedge A B. \text{rewrite } A B \implies \text{reflexive\_rewrite } A B$ 
  and  $\bigwedge A B. \text{reflexive\_rewrite } A B \implies \text{equalish } A B \vee \text{rewrite } A B$ 
  and  $\bigwedge A B C. \text{rewrite } A B \implies \text{rewrite } A C \implies \exists D. \text{rewrite } B D \wedge \text{rewrite } C$ 
   $D$ 
shows goal ⟨proof⟩

```

end

## 6 Some Isar command definitions

```

theory Commands
imports Main
keywords
  print_test :: diag and
  global_test :: thy_decl and
  local_test :: thy_decl
begin

```

### 6.1 Diagnostic command: no state change

⟨ML⟩

```

print_test x
print_test  $\lambda x. x = a$ 

```

### 6.2 Old-style global theory declaration

⟨ML⟩

```

global_test a
global_test b
print_test a

```

### 6.3 Local theory specification

$\langle ML \rangle$

```
local_test true = True
print_test true
thm true_def

local_test identity = λx. x
print_test identity x
thm identity_def

context fixes x y :: nat
begin

local_test test = x + y
print_test test
thm test_def

end

print_test test 0 1
thm test_def

end
```

## 7 The Drinker's Principle

```
theory Drinker
imports Main
begin
```

Here is another example of classical reasoning: the Drinker's Principle says that for some person, if he is drunk, everybody else is drunk!

We first prove a classical part of de-Morgan's law.

```
lemma de_Morgan:
assumes ¬ (forall x. P x)
shows ∃ x. ¬ P x
⟨proof⟩
```

```
theorem Drinker's_Principle: ∃ x. drunk x → (forall x. drunk x)
⟨proof⟩
```

end

## 8 Examples of function definitions

theory Functions

```
imports Main HOL-Library.Monad_Syntax
begin
```

## 8.1 Very basic

```
fun fib :: nat  $\Rightarrow$  nat
where
  fib 0 = 1
  | fib (Suc 0) = 1
  | fib (Suc (Suc n)) = fib n + fib (Suc n)
```

Partial simp and induction rules:

```
thm fib.psimps
thm fib.pinduct
```

There is also a cases rule to distinguish cases along the definition:

```
thm fib.cases
```

Total simp and induction rules:

```
thm fib.simps
thm fib.induct
```

Elimination rules:

```
thm fib.elims
```

## 8.2 Currying

```
fun add
where
  add 0 y = y
  | add (Suc x) y = Suc (add x y)
```

```
thm add.simps
```

**thm** add.induct — Note the curried induction predicate

## 8.3 Nested recursion

```
function nz
where
  nz 0 = 0
  | nz (Suc x) = nz (nz x)
  ⟨proof⟩
```

**lemma** nz\_is\_zero: — A lemma we need to prove termination

**assumes** trm: nz\_dom x

**shows** nz x = 0

⟨proof⟩

```
termination nz
```

$\langle proof \rangle$

```
thm nz.simps  
thm nz.induct
```

### 8.3.1 Here comes McCarthy's 91-function

```
function f91 :: nat ⇒ nat  
where  
  f91 n = (if 100 < n then n - 10 else f91 (f91 (n + 11)))  
 $\langle proof \rangle$ 
```

Prove a lemma before attempting a termination proof:

```
lemma f91_estimate:  
  assumes trm: f91_dom n  
  shows n < f91 n + 11  
 $\langle proof \rangle$ 
```

**termination**

$\langle proof \rangle$

Now trivial (even though it does not belong here):

```
lemma f91 n = (if 100 < n then n - 10 else 91)  
 $\langle proof \rangle$ 
```

### 8.3.2 Here comes Takeuchi's function

```
definition tak_m1 where tak_m1 = (λ(x,y,z). if x ≤ y then 0 else 1)  
definition tak_m2 where tak_m2 = (λ(x,y,z). nat (Max {x, y, z} - Min {x, y, z}))  
definition tak_m3 where tak_m3 = (λ(x,y,z). nat (x - Min {x, y, z}))
```

```
function tak :: int ⇒ int ⇒ int ⇒ int where  
  tak x y z = (if x ≤ y then y else tak (tak (x-1) y z) (tak (y-1) z x) (tak (z-1) x y))  
 $\langle proof \rangle$ 
```

**lemma tak\_pcorrect:**

$tak\_dom (x, y, z) \implies tak x y z = (\text{if } x \leq y \text{ then } y \text{ else if } y \leq z \text{ then } z \text{ else } x)$

**termination**

$\langle proof \rangle$

```
theorem tak_correct: tak x y z = (if x ≤ y then y else if y ≤ z then z else x)  
 $\langle proof \rangle$ 
```

## 8.4 More general patterns

### 8.4.1 Overlapping patterns

Currently, patterns must always be compatible with each other, since no automatic splitting takes place. But the following definition of GCD is OK, although patterns overlap:

```
fun gcd2 :: nat ⇒ nat ⇒ nat
where
  gcd2 x 0 = x
  | gcd2 0 y = y
  | gcd2 (Suc x) (Suc y) = (if x < y then gcd2 (Suc x) (y - x)
                                else gcd2 (x - y) (Suc y))

thm gcd2.simps
thm gcd2.induct
```

### 8.4.2 Guards

We can reformulate the above example using guarded patterns:

```
function gcd3 :: nat ⇒ nat ⇒ nat
where
  gcd3 x 0 = x
  | gcd3 0 y = y
  | gcd3 (Suc x) (Suc y) = gcd3 (Suc x) (y - x) if x < y
  | gcd3 (Suc x) (Suc y) = gcd3 (x - y) (Suc y) if ¬ x < y
  ⟨proof⟩
termination ⟨proof⟩

thm gcd3.simps
thm gcd3.induct
```

General patterns allow even strange definitions:

```
function ev :: nat ⇒ bool
where
  ev (2 * n) = True
  | ev (2 * n + 1) = False
  ⟨proof⟩
termination ⟨proof⟩

thm ev.simps
thm ev.induct
thm ev.cases
```

## 8.5 Mutual Recursion

```
fun evn od :: nat ⇒ bool
where
```

```

  evn 0 = True
| od 0 = False
| evn (Suc n) = od n
| od (Suc n) = evn n

```

```

thm evn.simps
thm od.simps

thm evn_od.induct
thm evn_od.termination

thm evn.elims
thm od.elims

```

## 8.6 Definitions in local contexts

```

locale my_monoid =
  fixes opr :: 'a  $\Rightarrow$  'a  $\Rightarrow$  'a
  and un :: 'a
  assumes assoc: opr (opr x y) z = opr x (opr y z)
  and lunit: opr un x = x
  and runit: opr x un = x
begin

  fun foldR :: 'a list  $\Rightarrow$  'a
  where
    foldR [] = un
  | foldR (x # xs) = opr x (foldR xs)

  fun foldL :: 'a list  $\Rightarrow$  'a
  where
    foldL [] = un
  | foldL [x] = x
  | foldL (x # y # ys) = foldL (opr x y # ys)

thm foldL.simps

lemma foldR_foldL: foldR xs = foldL xs
  {proof}

thm foldR_foldL

end

thm my_monoid.foldL.simps
thm my_monoid.foldR_foldL

```

## 8.7 fun\_cases

### 8.7.1 Predecessor

```
fun pred :: nat ⇒ nat
where
  pred 0 = 0
  | pred (Suc n) = n
```

**thm** *pred.elims*

**lemma**

```
assumes pred x = y
obtains x = 0 y = 0 | n where x = Suc n y = n
⟨proof⟩
```

If the predecessor of a number is 0, that number must be 0 or 1.

**fun\_cases** *pred0E[elim]*: *pred n = 0*

```
lemma pred n = 0 ⇒ n = 0 ∨ n = Suc 0
⟨proof⟩
```

Other expressions on the right-hand side also work, but whether the generated rule is useful depends on how well the simplifier can simplify it. This example works well:

**fun\_cases** *pred42E[elim]*: *pred n = 42*

```
lemma pred n = 42 ⇒ n = 43
⟨proof⟩
```

### 8.7.2 List to option

```
fun list_to_option :: 'a list ⇒ 'a option
where
  list_to_option [x] = Some x
  | list_to_option _ = None

fun_cases list_to_option_NoneE: list_to_option xs = None
  and list_to_option_SomeE: list_to_option xs = Some x

lemma list_to_option xs = Some y ⇒ xs = [y]
⟨proof⟩
```

### 8.7.3 Boolean Functions

```
fun xor :: bool ⇒ bool ⇒ bool
where
  xor False False = False
  | xor True True = False
  | xor _ _ = True
```

```
thm xor.elims
```

*fun\_cases* does not only recognise function equations, but also works with functions that return a boolean, e.g.:

```
fun_cases xor_TrueE: xor a b and xor_FalseE:  $\neg$ xor a b  
print_theorems
```

#### 8.7.4 Many parameters

```
fun sum4 :: nat  $\Rightarrow$  nat  $\Rightarrow$  nat  $\Rightarrow$  nat  $\Rightarrow$  nat  
where sum4 a b c d = a + b + c + d
```

```
fun_cases sum4_0E: sum4 a b c d = 0
```

```
lemma sum4 a b c d = 0  $\implies$  a = 0  
{proof}
```

### 8.8 Partial Function Definitions

Partial functions in the option monad:

```
partial_function (option)  
collatz :: nat  $\Rightarrow$  nat list option  
where  
collatz n =  
(if n  $\leq$  1 then Some [n]  
else if even n  
then do { ns  $\leftarrow$  collatz (n div 2); Some (n # ns) }  
else do { ns  $\leftarrow$  collatz (3 * n + 1); Some (n # ns)})  
  
declare collatz.simps[code]  
value collatz 23
```

Tail-recursive functions:

```
partial_function (tailrec) fixpoint :: ('a  $\Rightarrow$  'a)  $\Rightarrow$  'a  $\Rightarrow$  'a  
where  
fixpoint f x = (if f x = x then x else fixpoint f (f x))
```

### 8.9 Regression tests

The following examples mainly serve as tests for the function package.

```
fun listlen :: 'a list  $\Rightarrow$  nat  
where  
listlen [] = 0  
| listlen (x#xs) = Suc (listlen xs)
```

### 8.9.1 Context recursion

```
fun f :: nat ⇒ nat
where
  zero: f 0 = 0
  | succ: f (Suc n) = (if f n = 0 then 0 else f n)
```

### 8.9.2 A combination of context and nested recursion

```
function h :: nat ⇒ nat
where
  h 0 = 0
  | h (Suc n) = (if h n = 0 then h (h n) else h n)
  ⟨proof⟩
```

### 8.9.3 Context, but no recursive call

```
fun i :: nat ⇒ nat
where
  i 0 = 0
  | i (Suc n) = (if n = 0 then 0 else i n)
```

### 8.9.4 Tupled nested recursion

```
fun fa :: nat ⇒ nat ⇒ nat
where
  fa 0 y = 0
  | fa (Suc n) y = (if fa n y = 0 then 0 else fa n y)
```

### 8.9.5 Let

```
fun j :: nat ⇒ nat
where
  j 0 = 0
  | j (Suc n) = (let u = n in Suc (j u))
```

There were some problems with fresh names . . .

```
function k :: nat ⇒ nat
where
  k x = (let a = x; b = x in k x)
  ⟨proof⟩
```

```
function f2 :: (nat × nat) ⇒ (nat × nat)
where
  f2 p = (let (x,y) = p in f2 (y,x))
  ⟨proof⟩
```

### 8.9.6 Abbreviations

```
fun f3 :: 'a set ⇒ bool
```

```

where
 $f3\ x = \text{finite}\ x$ 

8.9.7 Simple Higher-Order Recursion

datatype 'a tree = Leaf 'a | Branch 'a tree list

fun treemap :: ('a  $\Rightarrow$  'a)  $\Rightarrow$  'a tree  $\Rightarrow$  'a tree
where
  treemap fn (Leaf n) = (Leaf (fn n))
  | treemap fn (Branch l) = (Branch (map (treemap fn) l))

fun tinc :: nat tree  $\Rightarrow$  nat tree
where
  tinc (Leaf n) = Leaf (Suc n)
  | tinc (Branch l) = Branch (map tinc l)

fun testcase :: 'a tree  $\Rightarrow$  'a list
where
  testcase (Leaf a) = [a]
  | testcase (Branch x) =
    (let xs = concat (map testcase x);
     ys = concat (map testcase x) in
     xs @ ys)

```

### 8.9.8 Pattern matching on records

```

record point =
  Xcoord :: int
  Ycoord :: int

function swp :: point  $\Rightarrow$  point
where
  swp () Xcoord = x, Ycoord = y () = () Xcoord = y, Ycoord = x ()
  ⟨proof⟩
termination ⟨proof⟩

```

### 8.9.9 The diagonal function

```

fun diag :: bool  $\Rightarrow$  bool  $\Rightarrow$  bool  $\Rightarrow$  nat
where
  diag x True False = 1
  | diag False y True = 2
  | diag True False z = 3
  | diag True True True = 4
  | diag False False False = 5

```

### 8.9.10 Many equations (quadratic blowup)

```

datatype DT =

```

```

A | B | C | D | E | F | G | H | I | J | K | L | M | N | P
| Q | R | S | T | U | V

fun big :: DT ⇒ nat
where
  big A = 0
  | big B = 0
  | big C = 0
  | big D = 0
  | big E = 0
  | big F = 0
  | big G = 0
  | big H = 0
  | big I = 0
  | big J = 0
  | big K = 0
  | big L = 0
  | big M = 0
  | big N = 0
  | big P = 0
  | big Q = 0
  | big R = 0
  | big S = 0
  | big T = 0
  | big U = 0
  | big V = 0

```

### 8.9.11 Automatic pattern splitting

```

fun f4 :: nat ⇒ nat ⇒ bool
where
  f4 0 0 = True
  | f4 _ _ = False

```

### 8.9.12 Polymorphic partial-function

```

partial_function (option) f5 :: 'a list ⇒ 'a option
where
  f5 x = f5 x
end

```

## 9 Gauss Numbers: integral gauss numbers

```

theory Gauss_Numbers
  imports HOL-Library.Centered_Division
begin

codatatype gauss = Gauss (Re: int) (Im: int)

```

```

lemma gauss_eqI [intro?]:
  ⟨ $x = y$  if ⟨ $\text{Re } x = \text{Re } y\text{Im } x = \text{Im } yproof⟩

lemma gauss_eq_iff:
  ⟨ $x = y \longleftrightarrow \text{Re } x = \text{Re } y \wedge \text{Im } x = \text{Im } yproof⟩

9.1 Basic arithmetic

instantiation gauss :: comm_ring_1
begin

  assumes  $\bigwedge n. R n \implies Q (\text{Suc } n)$ 
  shows R n Q n
  ⟨proof⟩
end

```

## 13 Textbook-style reasoning: the Knaster-Tarski Theorem

```

theory Knaster_Tarski
imports Main
begin

```

```
unbundle lattice_syntax
```

### 13.1 Prose version

According to the textbook [1, pages 93–94], the Knaster-Tarski fixpoint theorem is as follows.<sup>1</sup>

**The Knaster-Tarski Fixpoint Theorem.** Let  $L$  be a complete lattice and  $f: L \rightarrow L$  an order-preserving map. Then  $\bigcap \{x \in L \mid f(x) \leq x\}$  is a fixpoint of  $f$ .

**Proof.** Let  $H = \{x \in L \mid f(x) \leq x\}$  and  $a = \bigcap H$ . For all  $x \in H$  we have  $a \leq x$ , so  $f(a) \leq f(x) \leq x$ . Thus  $f(a)$  is a lower bound of  $H$ , whence  $f(a) \leq a$ . We now use this inequality to prove the reverse one (!) and thereby complete the proof that  $a$  is a fixpoint. Since  $f$  is order-preserving,  $f(f(a)) \leq f(a)$ . This says  $f(a) \in H$ , so  $a \leq f(a)$ .

### 13.2 Formal versions

The Isar proof below closely follows the original presentation. Virtually all of the prose narration has been rephrased in terms of formal Isar language elements. Just as many textbook-style proofs, there is a strong bias towards forward proof, and several bends in the course of reasoning.

---

<sup>1</sup>We have dualized the argument, and tuned the notation a little bit.

```

theorem Knaster_Tarski:
  fixes f :: 'a::complete_lattice  $\Rightarrow$  'a
  assumes mono f
  shows  $\exists a. f a = a$ 
  {proof}

```

Above we have used several advanced Isar language elements, such as explicit block structure and weak assumptions. Thus we have mimicked the particular way of reasoning of the original text.

In the subsequent version the order of reasoning is changed to achieve structured top-down decomposition of the problem at the outer level, while only the inner steps of reasoning are done in a forward manner. We are certainly more at ease here, requiring only the most basic features of the Isar language.

```

theorem Knaster_Tarski':
  fixes f :: 'a::complete_lattice  $\Rightarrow$  'a
  assumes mono f
  shows  $\exists a. f a = a$ 
  {proof}
end

```

## 14 Isabelle/ML basics

```

theory ML
  imports Main
begin

```

### 14.1 ML expressions

The Isabelle command **ML** allows to embed Isabelle/ML source into the formal text. It is type-checked, compiled, and run within that environment. Note that side-effects should be avoided, unless the intention is to change global parameters of the run-time environment (rare).

ML top-level bindings are managed within the theory context.

*{ML}*

### 14.2 Antiquotations

There are some language extensions (via antiquotations), as explained in the “Isabelle/Isar implementation manual”, chapter 0.

*{ML}*

Formal entities from the surrounding context may be referenced as follows:

**term** 1 + 1 — term within theory source

$\langle ML \rangle$

### 14.3 Recursive ML evaluation

$\langle ML \rangle$

### 14.4 IDE support

ML embedded into the Isabelle environment is connected to the Prover IDE.  
Poly/ML provides:

- precise positions for warnings / errors
- markup for defining positions of identifiers
- markup for inferred types of sub-expressions
- pretty-printing of ML values with markup
- completion of ML names
- source-level debugger

$\langle ML \rangle$

### 14.5 Example: factorial and ackermann function in Isabelle/ML

$\langle ML \rangle$

See <http://mathworld.wolfram.com/AckermannFunction.html>.

$\langle ML \rangle$

### 14.6 Parallel Isabelle/ML

Future.fork/join/cancel manage parallel evaluation.

Note that within Isabelle theory documents, the top-level command boundary may not be transgressed without special precautions. This is normally managed by the system when performing parallel proof checking.

$\langle ML \rangle$

The `Par_List` module provides high-level combinators for parallel list operations.

$\langle ML \rangle$

## 14.7 Function specifications in Isabelle/HOL

```
fun factorial :: nat ⇒ nat
where
  factorial 0 = 1
| factorial (Suc n) = Suc n * factorial n

term factorial 4 — symbolic term
value factorial 4 — evaluation via ML code generation in the background

declare [[ML_source_trace]]
⟨ML⟩
```

```
fun ackermann :: nat ⇒ nat ⇒ nat
where
  ackermann 0 n = n + 1
| ackermann (Suc m) 0 = ackermann m 1
| ackermann (Suc m) (Suc n) = ackermann m (ackermann (Suc m) n)

value ackermann 3 5

end
```

## 15 Peirce’s Law

```
theory Peirce
  imports Main
begin
```

We consider Peirce’s Law:  $((A \rightarrow B) \rightarrow A) \rightarrow A$ . This is an inherently non-intuitionistic statement, so its proof will certainly involve some form of classical contradiction.

The first proof is again a well-balanced combination of plain backward and forward reasoning. The actual classical step is where the negated goal may be introduced as additional assumption. This eventually leads to a contradiction.<sup>2</sup>

```
theorem ((A → B) → A) → A
⟨proof⟩
```

In the subsequent version the reasoning is rearranged by means of “weak assumptions” (as introduced by **presume**). Before assuming the negated goal  $\neg A$ , its intended consequence  $A \rightarrow B$  is put into place in order to solve the main problem. Nevertheless, we do not get anything for free, but have to establish  $A \rightarrow B$  later on. The overall effect is that of a logical *cut*.

---

<sup>2</sup>The rule involved there is negation elimination; it holds in intuitionistic logic as well.

Technically speaking, whenever some goal is solved by **show** in the context of weak assumptions then the latter give rise to new subgoals, which may be established separately. In contrast, strong assumptions (as introduced by **assume**) are solved immediately.

**theorem**  $((A \rightarrow B) \rightarrow A) \rightarrow A$   
 $\langle proof \rangle$

Note that the goals stemming from weak assumptions may be even left until **qed** time, where they get eventually solved “by assumption” as well. In that case there is really no fundamental difference between the two kinds of assumptions, apart from the order of reducing the individual parts of the proof configuration.

Nevertheless, the “strong” mode of plain assumptions is quite important in practice to achieve robustness of proof text interpretation. By forcing both the conclusion *and* the assumptions to unify with the pending goal to be solved, goal selection becomes quite deterministic. For example, decomposition with rules of the “case-analysis” type usually gives rise to several goals that only differ in their local contexts. With strong assumptions these may be still solved in any order in a predictable way, while weak ones would quickly lead to great confusion, eventually demanding even some backtracking.

**end**

## 16 Using extensible records in HOL – points and coloured points

```
theory Records
  imports Main
begin
```

### 16.1 Points

```
record point =
  xpos :: nat
  ypos :: nat
```

Apart many other things, above record declaration produces the following theorems:

```
thm point.simps
thm point.iffs
thm point.defs
```

The set of theorems *point.simps* is added automatically to the standard simpset, *point.iffs* is added to the Classical Reasoner and Simplifier context.

Record declarations define new types and type abbreviations:

```

point = (xpos :: nat, ypos :: nat) = () point_ext_type
'a point_scheme = (xpos :: nat, ypos :: nat, ... :: 'a) = 'a point_ext_type

consts foo2 :: (xpos :: nat, ypos :: nat)
consts foo4 :: 'a ⇒ (xpos :: nat, ypos :: nat, ... :: 'a)

```

### 16.1.1 Introducing concrete records and record schemes

```

definition foo1 :: point
  where foo1 = (xpos = 1, ypos = 0)

definition foo3 :: 'a ⇒ 'a point_scheme
  where foo3 ext = (xpos = 1, ypos = 0, ... = ext)

```

### 16.1.2 Record selection and record update

```

definition getX :: 'a point_scheme ⇒ nat
  where getX r = xpos r

definition setX :: 'a point_scheme ⇒ nat ⇒ 'a point_scheme
  where setX r n = r (xpos := n)

```

### 16.1.3 Some lemmas about records

Basic simplifications.

```

lemma point.make n p = (xpos = n, ypos = p)
  ⟨proof⟩

lemma xpos (xpos = m, ypos = n, ... = p) = m
  ⟨proof⟩

lemma (xpos = m, ypos = n, ... = p)(xpos:= 0) = (xpos = 0, ypos = n, ... =
p)
  ⟨proof⟩

```

Equality of records.

```

lemma n = n' ⇒ p = p' ⇒ (xpos = n, ypos = p) = (xpos = n', ypos = p')
  — introduction of concrete record equality
  ⟨proof⟩

lemma (xpos = n, ypos = p) = (xpos = n', ypos = p') ⇒ n = n'
  — elimination of concrete record equality
  ⟨proof⟩

lemma r(xpos := n)(ypos := m) = r(ypos := m)(xpos := n)
  — introduction of abstract record equality
  ⟨proof⟩

```

**lemma**  $r(\text{xpos} := n) = r(\text{xpos} := n')$  if  $n = n'$   
 — elimination of abstract record equality (manual proof)  
 $\langle \text{proof} \rangle$

Surjective pairing

**lemma**  $r = (\text{xpos} = \text{xpos } r, \text{ypos} = \text{ypos } r)$   
 $\langle \text{proof} \rangle$

**lemma**  $r = (\text{xpos} = \text{xpos } r, \text{ypos} = \text{ypos } r, \dots = \text{point.more } r)$   
 $\langle \text{proof} \rangle$

Representation of records by cases or (degenerate) induction.

**lemma**  $r(\text{xpos} := n)(\text{ypos} := m) = r(\text{ypos} := m)(\text{xpos} := n)$   
 $\langle \text{proof} \rangle$

**lemma**  $r(\text{xpos} := n)(\text{ypos} := m) = r(\text{ypos} := m)(\text{xpos} := n)$   
 $\langle \text{proof} \rangle$

**lemma**  $r(\text{xpos} := n)(\text{xpos} := m) = r(\text{xpos} := m)$   
 $\langle \text{proof} \rangle$

**lemma**  $r(\text{xpos} := n)(\text{xpos} := m) = r(\text{xpos} := m)$   
 $\langle \text{proof} \rangle$

Concrete records are type instances of record schemes.

**definition**  $\text{foo5} :: \text{nat}$   
**where**  $\text{foo5} = \text{getX } (\text{xpos} = 1, \text{ypos} = 0)$

Manipulating the “...” (more) part.

**definition**  $\text{incX} :: 'a \text{ point\_scheme} \Rightarrow 'a \text{ point\_scheme}$   
**where**  $\text{incX } r = (\text{xpos} = \text{xpos } r + 1, \text{ypos} = \text{ypos } r, \dots = \text{point.more } r)$

**lemma**  $\text{incX } r = \text{setX } r (\text{Suc } (\text{ getX } r))$   
 $\langle \text{proof} \rangle$

An alternative definition.

**definition**  $\text{incX}' :: 'a \text{ point\_scheme} \Rightarrow 'a \text{ point\_scheme}$   
**where**  $\text{incX}' r = r(\text{xpos} := \text{xpos } r + 1)$

## 16.2 Coloured points: record extension

**datatype**  $\text{colour} = \text{Red} \mid \text{Green} \mid \text{Blue}$

```
record cpoint = point +
    colour :: colour
```

The record declaration defines a new type constructor and abbreviations:

```
cpoint = (xpos :: nat, ypos :: nat, colour :: colour) =
    () cpoint_ext_type point_ext_type
'a cpoint_scheme = (xpos :: nat, ypos :: nat, colour :: colour, ... :: 'a) =
    'a cpoint_ext_type point_ext_type
```

```
consts foo6 :: cpoint
consts foo7 :: (xpos :: nat, ypos :: nat, colour :: colour)
consts foo8 :: 'a cpoint_scheme
consts foo9 :: (xpos :: nat, ypos :: nat, colour :: colour, ... :: 'a)
```

Functions on *point* schemes work for *cpoints* as well.

```
definition foo10 :: nat
    where foo10 = getX (xpos = 2, ypos = 0, colour = Blue)
```

### 16.2.1 Non-coercive structural subtyping

Term *foo11* has type *cpoint*, not type *point* — Great!

```
definition foo11 :: cpoint
    where foo11 = setX (xpos = 2, ypos = 0, colour = Blue) 0
```

## 16.3 Other features

Field names contribute to record identity.

```
record point' =
    xpos' :: nat
    ypos' :: nat
```

May not apply *getX* to (xpos' = 2, ypos' = 0) — type error.

Polymorphic records.

```
record 'a point'' = point +
    content :: 'a
```

```
type_synonym cpoint'' = colour point''
```

Updating a record field with an identical value is simplified.

```
lemma r(xpos := xpos r) = r
    ⟨proof⟩
```

Only the most recent update to a component survives simplification.

```
lemma r(xpos := x, ypos := y, xpos := x') = r(ypos := y, xpos := x')
    ⟨proof⟩
```

In some cases it's convenient to automatically split (quantified) records. For this purpose there is the simproc `Record.split_simproc` and the tactic `Record.split_simp_tac`. The simplification procedure only splits the records, whereas the tactic also simplifies the resulting goal with the standard record simplification rules. A (generalized) predicate on the record is passed as parameter that decides whether or how ‘deep’ to split the record. It can peek on the subterm starting at the quantified occurrence of the record (including the quantifier). The value 0 indicates no split, a value greater 0 splits up to the given bound of record extension and finally the value  $\sim 1$  completely splits the record. `Record.split_simp_tac` additionally takes a list of equations for simplification and can also split fixed record variables.

```
lemma  $(\forall r. P (\text{xpos } r)) \longrightarrow (\forall x. P x)$ 
    <proof>
```

```
lemma  $(\forall r. P (\text{xpos } r)) \longrightarrow (\forall x. P x)$ 
    <proof>
```

```
lemma  $(\exists r. P (\text{xpos } r)) \longrightarrow (\exists x. P x)$ 
    <proof>
```

```
lemma  $(\exists r. P (\text{xpos } r)) \longrightarrow (\exists x. P x)$ 
    <proof>
```

```
lemma  $\bigwedge r. P (\text{xpos } r) \implies (\exists x. P x)$ 
    <proof>
```

```
lemma  $\bigwedge r. P (\text{xpos } r) \implies (\exists x. P x)$ 
    <proof>
```

```
lemma  $P (\text{xpos } r) \implies (\exists x. P x)$ 
    <proof>
```

```
notepad
begin
    <proof>
end
```

The effect of simproc `Record.ex_sel_eq_simproc` is illustrated by the following lemma.

```
lemma  $\exists r. \text{xpos } r = x$ 
    <proof>
```

## 16.4 Simprocs for update and equality

```
record alph1 =
  a :: nat
  b :: nat
```

```

record alph2 = alph1 +
  c :: nat
  d :: nat

record alph3 = alph2 +
  e :: nat
  f :: nat

```

The simprocs that are activated by default are:

- `Record.simpsproc`: field selection of (nested) record updates.
- `Record.upd_simproc`: nested record updates.
- `Record.eq_simproc`: (componentwise) equality of records.

By default record updates are not ordered by simplification.

```

schematic_goal r(b := x, a := y) = ?X
  ⟨proof⟩

```

Normalisation towards an update ordering (string ordering of update function names) can be configured as follows.

```

schematic_goal r(b := y, a := x) = ?X
  ⟨proof⟩

```

Note the interplay between update ordering and record equality. Without update ordering the following equality is handled by `Record.eq_simproc`. Record equality is thus solved by componentwise comparison of all the fields of the records which can be expensive in the presence of many fields.

```

lemma r(f := x1, a := x2) = r(a := x2, f := x1)
  ⟨proof⟩

```

```

lemma r(f := x1, a := x2) = r(a := x2, f := x1)
  ⟨proof⟩

```

With update ordering the equality is already established after update normalisation. There is no need for componentwise comparison.

```

lemma r(f := x1, a := x2) = r(a := x2, f := x1)
  ⟨proof⟩

```

```

schematic_goal r(f := x1, e := x2, d := x3, c := x4, b := x5, a := x6) = ?X
  ⟨proof⟩

```

```

schematic_goal r(f := x1, e := x2, d := x3, c := x4, e := x5, a := x6) = ?X
  ⟨proof⟩

```

```

schematic_goal r(f := x1, e := x2, d := x3, c := x4, e := x5, a := x6) = ?X
  ⟨proof⟩

```

## 16.5 A more complex record expression

```
record ('a, 'b, 'c) bar = bar1 :: 'a
       bar2 :: 'b
       bar3 :: 'c
       bar21 :: 'b × 'a
       bar32 :: 'c × 'b
       bar31 :: 'c × 'a

print_record ('a,'b,'c) bar
```

## 16.6 Some code generation

```
export_code foo1 foo3 foo5 foo10 checking SML
```

Code generation can also be switched off, for instance for very large records:

```
declare [[record_codegen = false]]
```

```
record not_so_large_record =
  bar520 :: nat
  bar521 :: nat × nat
```

$\langle ML \rangle$

```
declare [[record_codegen]]
```

```
schematic_goal ‹fld_1 (r@{fld_300 := x300, fld_20 := x20, fld_200 := x200}) = ?X›
⟨proof⟩
```

```
schematic_goal ‹r@{fld_300 := x300, fld_20 := x20, fld_200 := x200} = ?X›
⟨proof⟩
```

```
end
```

```
theory Rewrite_Examples
imports Main HOL-Library.Rewrite
begin
```

## 17 The rewrite Proof Method by Example

This theory gives an overview over the features of the pattern-based rewrite proof method.

Documentation: <https://arxiv.org/abs/2111.04082>

## 18 Finite sequences

```
theory Seq
  imports Main
begin

datatype 'a seq = Empty | Seq 'a 'a seq

fun conc :: 'a seq ⇒ 'a seq ⇒ 'a seq
where
  conc Empty ys = ys
  | conc (Seq x xs) ys = Seq x (conc xs ys)

fun reverse :: 'a seq ⇒ 'a seq
where
  reverse Empty = Empty
  | reverse (Seq x xs) = conc (reverse xs) (Seq x Empty)

lemma conc_empty: conc xs Empty = xs
⟨proof⟩

lemma conc_assoc: conc (conc xs ys) zs = conc xs (conc ys zs)
⟨proof⟩

lemma reverse_conc: reverse (conc xs ys) = conc (reverse ys) (reverse xs)
⟨proof⟩

lemma reverse_reverse: reverse (reverse xs) = xs
⟨proof⟩

end
```

## 19 Square roots of primes are irrational

```
theory Sqrt
  imports Complex_Main HOL-Computational_Algebra.Primes
begin

The square root of any prime number (including 2) is irrational.
```

```
theorem sqrt_prime_irrational:
  fixes p :: nat
  assumes prime p
  shows sqrt p ∉ ℚ
⟨proof⟩
```

```
corollary sqrt_2_not_rat: sqrt 2  $\notin \mathbb{Q}$ 
  ⟨proof⟩
```

Here is an alternative version of the main proof, using mostly linear forward-reasoning. While this results in less top-down structure, it is probably closer to proofs seen in mathematics.

```
theorem
```

```
  fixes p :: nat
  assumes prime p
  shows sqrt p  $\notin \mathbb{Q}$ 
  ⟨proof⟩
```

Another old chestnut, which is a consequence of the irrationality of  $\sqrt{2}$ .

```
lemma  $\exists a b::real. a \notin \mathbb{Q} \wedge b \notin \mathbb{Q} \wedge a \text{ powr } b \in \mathbb{Q}$  (is  $\exists a b. ?P a b$ )
  ⟨proof⟩
```

```
end
```
